INTRODUCTION:

The data contained in this report were obtained for the U.S. Coast Guard under MIPR DTCG - 23 - 83-F-20033. A 1:32 scale model of the 157 foot coastal buoy tender (WLM) was tested in deep and shallow calm water, regular and irregular, long crested, head seas at the U.S. Naval Academy Hydromechanics Laboratory. All tests were conducted at model conditions corresponding to a full scale ship displacement of 471 long tons, zero static trim, six (6) foot draft, and a pitch gyroradius of 37.45 feet (25% of L_{WL}). Calm water tests covered a range of model speeds corresponding to a full scale ship speed range of seven (7) to fifteen (15) knots. Seakeeping tests were run at two discrete model speeds which correspond to 8.2 knots and 12.2 knots for the full scale ship. In calm water, model speed, total model resistance, sinkage and trim were measured. In regular waves, model speed, total model resistance, pitch, heave, and relative bow motion at Station 1 were measured. In irregular waves, model speed, total model resistance, pitch, and heave were measured.

TEST PROCEDURE:

A 1:32 scale model was built according to lines provided by the U.S. Coast Guard by the U.S. Naval Academy's Technical Support Department, and tested in the 120 foot towing tank at the U.S. Naval Academy Hydromechanics Laboratory (NAHL).

Characteristics for both the model and ship are given in Table 1. The 120 foot towing tank is described in Figure 1. The lines from which the model was fabricated (using FASTSHIP and the numerically controlled milling machine) are shown in Figure 2. Propeller tunnels, scaled from "as built" USCG drawings, were manually carved into the hull subsequent to the FASTSHIP/NC milling process. The model was constructed of six-pound, closed-cell foam, coated with a thin fiberglass shell.

Turbulence stimulation was accomplished using a single row of studs. The model was dynamically ballasted so that the model pitch gyroradius (in air) was set to be 25% of the waterline length. Figure 3 shows the outfitted and ballasted model ready for mounting on the carriage. When mounted under the carriage in the 120 foot towing tank, the model was free to heave and pitch. Figure 4 shows the model mounted and aligned under the 120 foot tank carriage ready for testing. For regular wave testing, a nominally constant wave steepness, H_w/L_w , of 1/50 was maintained for Test 135 and 1/60 for the later testing, Test 322. The encountered wave was measured using a sonic probe mounted on the carriage. All test data were acquired using the NAHL computer-based data acquisition system.

TABLE 1
157 FOOT WLM CHARACTERISTICS

	<u>SHIP</u>	<u>MODEL ($\lambda=32$)</u>
Length Overall	157.0 ft.	58.88 in.
Waterline Length	150.1 ft.	56.28 in.
Displacement ¹	471.1 LT	31.33 lb.
Wetted Surface	4530.2 sq. ft	637.06 sq. in.
LCG ²	2.1 ft.	0.79 in.
Pitch Gyradius ³	37.5 ft.	14.06 in.

Notes:

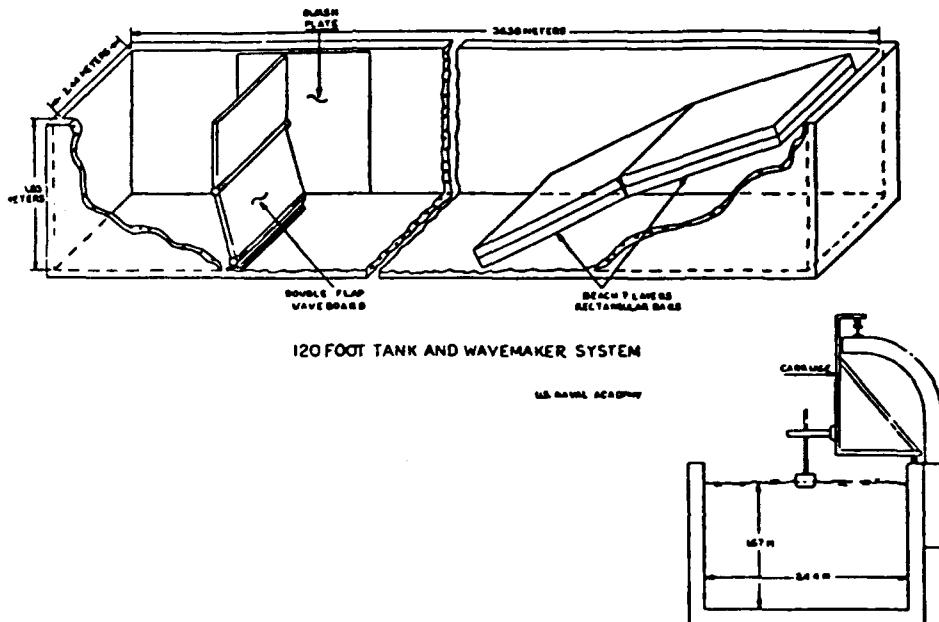

1. Ship displacement for 59° F, salt water; model displacement for 68° F, fresh water.
2. LCG is referenced to amidships; positive values indicate G forward of amidships. Values in the table correspond to zero static trim.
3. 25% of the waterline length.

CALM WATER TEST RESULTS:

A total of 48 runs were made in deep* water under test numbers 323 and 443 in December, 1989 and September, 1988 respectively. The cumulative tabulations and computer plots of these data are given in Appendix A. Blockage effects on model resistance in deep water were ignored since the ratio of tank cross-sectional area was 0.39%, well below the 0.5% rule of thumb. Employing Froude scaling, the ITTC 1957 frictional resistance coefficient, and a correlation allowance of 0.0005, these data were expanded, without any intermediate fairing, to effective horsepower (EHP) and running trim angle (τ). EHP and τ are plotted against ship speed (Vs) in Figure 5. The open and solid symbols differentiate the data from the two totally independent tests performed more than a year apart. The repeatability appears to be excellent. Rise and sinkage at the perpendiculars are computed from the measured trim angle, the measured rise and sinkage at the towing point, and the model setup parameters. Throughout the speed range investigated, the ship squats with a slight bow down attitude as can be seen from Figure 6. Only the data from Test 323 are shown in Figure 6. Excessive data scatter on the rise/sinkage channel during Test 443 caused by tank water level changes and inconsistent rezeroing techniques was responsible for their omission from Figure 6.

The significant effects of operating in shallow water are shown in Figures 7 and 8. Both propulsive power requirements and ship attitudinal changes speed are drastically affected by water depth. For the trends shown in Figures 7 and 8, impervious, smooth, horizontal bottom conditions existed. Application of such trends to operation in waters where bottoms are not so easily defined should be made with caution. To facilitate comparison to other shallow water data or to analytical methods like the classical work of Schlichting, auxiliary scales of Froude number based on water depth ($F_{Nh} = v/\sqrt{gh}$), are shown on Figure 7. While trim angle and rise/sinkage at the perpendiculars appear well behaved at low speeds, considerable confusion develops at $F_{Nh} = 0.8$ for both depths tested. This behavior corresponds to the severe slope change in the EHP curve for both depths. Experimentation in shallow water at speeds approaching the critical speed (i.e., $F_{Nh} = 1.0$), is complicated by the fact that the hull generated wave system tends to be non-steady. That is, the widening of the Kelvin wave angle takes time which is not always available in a limited tank length. This is an area which needs experimental and theoretical attention.

*Tank water depth of 60 inches, which for this model corresponds to 160 feet for the ship.

SEAKEEPING RESULTS:

Table 2 is a summary of the measured, unsquared model data acquired during long crested, regular, head sea testing in the 120 foot towing tank. The model was ballasted as indicated in Table 1. The bifilar suspension method was used to set the longitudinal gyroradius (k_{zz}).

Figure 9 is a plot of the normalized pitch response for three model speeds versus model encounter frequency. A pitch resonance around 1.34 Hz can be seen. No unusual behavior is noted from the pitch response curves. It is somewhat surprising that the peak of the highest speed response curve (\square) does not exceed that of the middle speed curve (Δ). To develop ship scale values from Figure 9, the following are presented:

$$\left[\frac{\theta(\text{deg})}{H_w \text{ (ft)}} \right] \text{SHIP} = \left[\frac{\theta(\text{deg})}{H_w \text{ (ft)}} \right] \text{MODEL} \times \lambda^{-1}$$

$$[f_e(\text{Hz})] \text{SHIP} = [f_e(\text{Hz})] \text{MODEL} \times \lambda^{-1/2}$$

$$[v(\text{knots})] \text{SHIP} = [v(\text{fps})] \text{MODEL} \times \lambda^{1/2} / 1.688$$

where $\lambda = L_{\text{SHIP}} / L_{\text{MODEL}}$

U.S. NAVAL ACADEMY
HYDROMECHANICS LABORATORY
120° TANK RESULTS

FIGURE 9: Normalized Pitch Response versus Model Encounter Frequency for 157° WLM at Three Model Speeds

If nondimensional format for normalized pitch response is preferred,

$$[\text{Pitch/Wave Slope}] = \left[\frac{2\theta \text{ (deg)}}{H_w \text{ (ft)}} \right] \times \frac{L_w \text{ (ft)}}{360}$$

where wave slope is $\pi H_w / L_w$ (radians)

Figure 10 is a plot of the normalized heave response for the same three model speeds versus model encounter frequency. The curves show a consistent trend of increasing motion as speed increases. The apparent resonant frequency in heave is about 1.38 Hz. All curves decay to zero reasonably at high frequencies. To develop ship scale values from Figure 10, the following is presented:

$$\left[\frac{2z \text{ (ft)}}{H_w \text{ (ft)}} \right] \text{ SHIP} = \left[\frac{2z \text{ (ft)}}{H_w \text{ (ft)}} \right] \text{ MODEL}$$

Encounter frequency and speed scale as given earlier.

Figure 11 is a plot of the normalized relative vertical motion between the hull and the water surface at Station 1, which, for this ship, is the forward end of the bulwark cutout in way of the buoy work deck. Unlike the previous two responses (pitch and heave), which are absolute motions, relative bow motion, RBM, is in effect, dynamic local freeboard and local draft. This response is observed visually as the model moves down the tank using the vertical scale affixed to the side of the model at Station 1 (see Figures 3 and 4). RBM data were acquired for the lowest and highest model speed conditions only. The normalized response curves shown in Figure 11 are reasonable in shape and magnitude. To develop ship scale values for normalized RBM response, proceed exactly as for heave; i.e.,

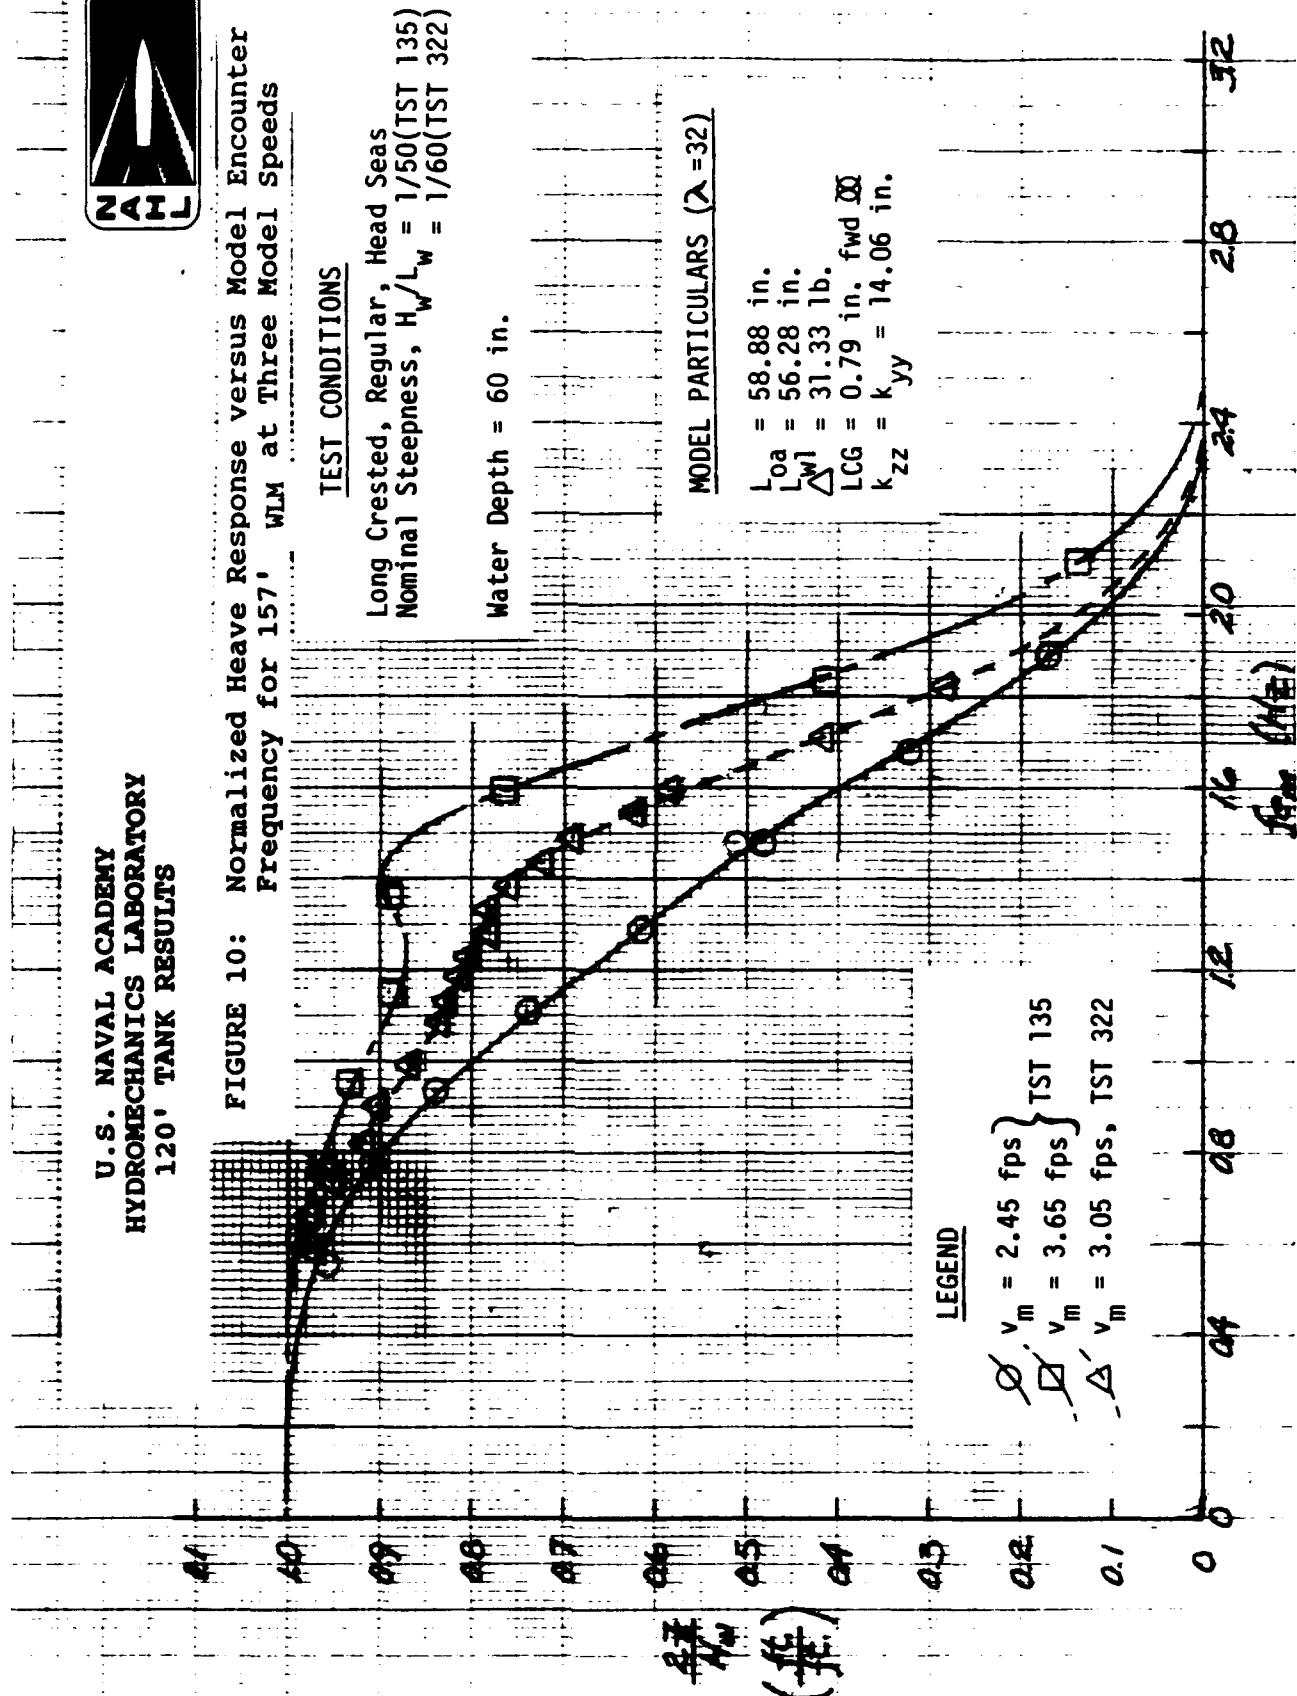

$$\left[\frac{\text{RBM} \text{ (ft)}}{H_w \text{ (ft)}} \right] \text{ SHIP} = \left[\frac{\text{RBM} \text{ (ft)}}{H_w \text{ (ft)}} \right] \text{ MODEL}$$

Table 3 contains the parameters and data used to compute the normalized added resistance due to waves in regular, long crested, head seas at each of three model speeds. The values of the still water total model resistance coefficient for each of the speeds were read from a curve faired through C_{Tm} data from Tests 323 and 443 (Appendix A). Figure 12 is a plot of the normalized added resistance due to waves at each of three model speeds versus model encounter frequency. The data scatter is considerably greater for this response than for pitch or heave shown earlier, especially near the peak responses. No apparent order based on model speed can be deduced from Figure 8. The curves peak between 1.5 Hz and 1.7 Hz - roughly between the absolute motions (pitch and heave) and the relative bow motion. To develop ship scale values from Figure 12, the following is presented:

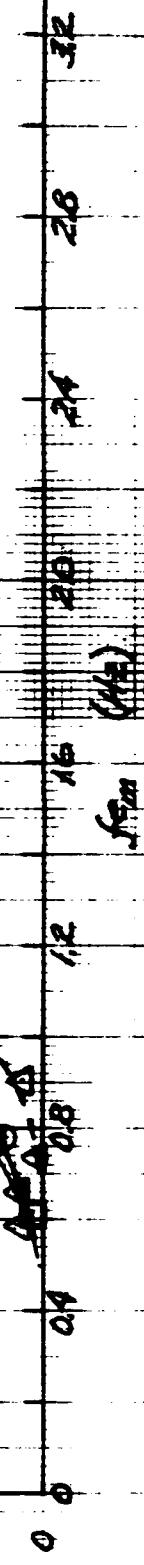

FIGURE 12: Normalized Added Resistance due to Encountered Waves
versus Model Encounter Frequency for 157' WLM at Three Model Speeds

$$\left[\frac{R_{AW}(\text{lbs})}{Hw^2(\text{ft}^2)} \right]_{\text{SHIP}} = \left[\frac{R_{AW}(\text{lbs})}{Hw^2(\text{ft}^2)} \right]_{\text{MODEL}} \times \lambda \times \frac{\rho_{\text{SHIP}}}{\rho_{\text{MODEL}}}$$

Encounter frequency and speed scale as given earlier. R_{AW} is assumed to scale as λ^3 since it is treated as is residuary resistance. The cumulative tabular and graphical summaries of measured model data for tests is regular, long crested, head waves are contained in Appendix B. These data are unfaired and come directly from the acquisition and analysis software with no interpretation by the test engineer. They are provided to permit the reader to interpret the data as he or she sees fit.

Irregular, long crested, head sea testing was also performed on the WAGL model in the 120 ft. towing tank. An irregular wave system satisfying the model scale, stationary spectrum shown in Figure 13 was developed and used. This spectrum represents Sea State 3 for the 1:32 scale of the subject model. Discrete model speeds of 2.45 fps and 3.65 fps were run. Table 4 summarizes the statistical results obtained.

DATA BASE:

The cumulative tabular and graphical summaries of measured data at model scale are contained in Appendices A and B. These data are unfaired and come directly from the acquisition and analysis software with no interpretation by the test engineer. They are provided to permit the reader to interpret the data as he or she sees fit.

ACKNOWLEDGMENTS:

The author would like to acknowledge Mr. Steve Enzinger and midshipmen naval architects of the Class of 1988 for conducting the experimental work described herein.
